Section 1

One-Way Functions
Informal discussion

A one-way function (OWF) is:
- Easy to compute, everywhere
- Hard to invert, on the average

Why should we care about OWFs?
- Hidden in (almost) any cryptographic primitive: necessary for “cryptography"
- Sufficient for many cryptographic primitives
Formal definition

Definition 1 (one-way functions (OWFs))

A polynomial-time computable function \( f : \{0, 1\}^* \mapsto \{0, 1\}^* \) is one-way, if
\[
\Pr_{x \leftarrow \{0,1\}^n} [A(1^n, f(x)) \in f^{-1}(f(x)))] = \text{neg}(n)
\]
for any PPT \( A \).

- polynomial-time computable: there exists polynomial-time algorithm \( F \), such that \( F(x) = f(x) \) for every \( x \in \{0, 1\}^* \).
- \text{neg}: a function \( \mu : \mathbb{N} \mapsto [0, 1] \) is a negligible function of \( n \), denoted \( \mu(n) = \text{neg}(n) \), if for any \( p \in \text{poly} \) there exists \( n' \in \mathbb{N} \) such that \( \mu(n) < 1/p(n) \) for all \( n > n' \).
- \( x \leftarrow \{0, 1\}^n \): \( x \) is uniformly drawn from \( \{0, 1\}^n \).
- PPT: probabilistic polynomial-time algorithm.

We typically omit \( 1^n \) from the input list of \( A \).
Formal definition cont.

1. Is this the right definition?
   - Asymptotic
   - Efficiently computable
   - On the average
   - Only against PPT's

2. OWF $\implies \mathcal{P} \neq \mathcal{NP}$

3. Does $\mathcal{P} \neq \mathcal{NP} \implies$ OWF?

4. (most) Crypto implies OWFs

5. Do OWFs imply Crypto?

6. Where do we find them?

7. Non uniform OWFs

Definition 2 (Non-uniform OWF))

A polynomial-time computable function $f : \{0, 1\}^* \mapsto \{0, 1\}^*$ is non-uniformly one-way, if

$$\Pr_{x \leftarrow \{0,1\}^n} \left[ C_n(f(x)) \in f^{-1}(f(x)) \right] = \neg(n)$$

for any polynomial-size family of circuits $\{C_n\}_{n \in \mathbb{N}}$. 
Length-preserving functions

**Definition 3 (length preserving functions)**

A function \( f : \{0, 1\}^{\ast} \rightarrow \{0, 1\}^{\ast} \) is length preserving, if \( |f(x)| = |x| \) for every \( x \in \{0, 1\}^{\ast} \)

**Theorem 4**

Assume that OWFs exit, then there exist length-preserving OWFs.

Proof idea: use the assumed OWF to create a length preserving one.
Partial domain functions

**Definition 5 (Partial domain functions)**

For $m, \ell : \mathbb{N} \mapsto \mathbb{N}$, let $f : \{0, 1\}^{\ell(n)} \mapsto \{0, 1\}^{m(n)}$ denote a function defined over input lengths in $\{\ell(n)\}_{n \in \mathbb{N}}$, and maps strings of length $\ell(n)$ to strings of length $m(n)$.

Such function is efficient, if it is poly-time computable and $\ell$ is polynomial time computable and bounded.

The definition of one-wayness naturally extends to such (efficient) functions.
OWFs imply length-preserving OWFs cont.

Let $f : \{0, 1\}^* \mapsto \{0, 1\}^*$ be a OWF, let $p \in \text{poly}$ be a bound on its computing-time, and assume wlg. that $p$ is monotony increasing (can we?).

**Construction 6 (the length preserving function)**

Define $g : \{0, 1\}^{p(n)+1} \mapsto \{0, 1\}^{p(n)+1}$ as

$$g(x) = f(x_1, \ldots, n), 1, 0^{p(n)-|f(x_1, \ldots, n)|}$$

Note that $g$ is well defined, length preserving and efficient.

**Claim 7**

$g$ is one-way.

How can we prove that $g$ is one-way?

Answer: using reduction.
Proving that $g$ is one-way

Proof: Assume that $g$ is not one-way. Namely, there exists PPT $A$, $q \in \text{poly}$ and infinite set $\mathcal{I} \subseteq \{p(n) + 1 : n \in \mathbb{N}\}$, with

$$\Pr_{x \leftarrow \{0,1\}^{n'}} \left[ A(1^{n'}, y) \in g^{-1}(g(x)) \right] > 1/q(n')$$

(1)

for every $n' \in \mathcal{I}$.

We show how to use $A$ for inverting $f$.

Claim 8

$w \in g^{-1}(y, 1, 0^{p(n)-|y|}) \implies w_1, \ldots, n \in f^{-1}(y)$

Proof: Since $g(w) = f(w_1, \ldots, n), 1, 0^{p(n)-|f(w_1, \ldots, n)|} = y, 1, 0^{p(n)-|y|}$, it follows that $f(w_1, \ldots, n) = y$ (??). □
**Algorithm 9 (Inverter B for f)**

Input: $1^n$ and $y \in \{0, 1\}^*$

1. Let $x = A(1^{p(n)+1}, y, 1, 0^{p(n)} - |y|)$
2. Return $x_1, \ldots, n$

**Claim 10**

Let $\mathcal{I}' := \{n \in \mathbb{N} : p(n) + 1 \in \mathcal{I}\}$. Then

1. $\mathcal{I}'$ is infinite
2. $\Pr_{x \leftarrow \{0,1\}^n}[B(1^n, f(x)) \in f^{-1}(f(x))], > 1/q(p(n) + 1)$ for every $n \in \mathcal{I}'$

This contradicts the assumed one-wayness of $f$. □

Proof: (1) is clear, (2)

$$\Pr_{x \leftarrow \{0,1\}^n} \left[ B(1^n, f(x)) \in f^{-1}(f(x)) \right]$$

$$= \Pr_{x \leftarrow \{0,1\}^n} \left[ A(1^{p(n)+1}, f(x), 0^{p(n)} - n)_{1, \ldots, n} \in f^{-1}(f(x)) \right]$$

$$= \Pr_{x' \leftarrow \{0,1\}^{p(n)+1}} \left[ A(1^{p(n)+1}, g(x'))_{1, \ldots, n} \in f^{-1}(f(x')) \right]$$

$$\geq \Pr_{x' \leftarrow \{0,1\}^{p(n)+1}} \left[ A(1^{p(n)+1}, g(x')) \in g^{-1}(g(x')) \right] \geq 1/q(p(n) + 1).$$
From partial-domain length-preserving OWFs to length-preserving OWFs

**Construction 11**

Given a function \( f: \{0, 1\}^{\ell(n)} \mapsto \{0, 1\}^{\ell(n)} \), define \( f_{\text{all}}: \{0, 1\}^n \mapsto \{0, 1\}^n \) as

\[
f_{\text{all}}(x) = f(x_1, \ldots, k), 0^{n-k}
\]

where \( n = |x| \) and \( k := \max\{\ell(n') \leq n: n' \in [n]\} \).

Clearly, \( f_{\text{all}} \) is length preserving, defined for every input length, and efficient if \( f \) is.

**Claim 12**

Assume \( f \) is efficient, \( f \) is one-way, and \( \ell \) satisfies \( 1 \leq \frac{\ell(n+1)}{\ell(n)} \leq p(n) \) for some \( p \in \text{poly} \), then \( f_{\text{all}} \) is one-way function.

Proof: ?

We conclude that the existence of OWF implies the existence of length-preserving OWF that is defined over all input lengths.
Few remarks

More “security-preserving” reductions exits.

Convention for rest of the talk

Let $f : \{0, 1\}^n \mapsto \{0, 1\}^n$ be a one-way function.
Weak one-way functions

**Definition 13 (weak one-way functions)**

A poly-time computable function \( f : \{0, 1\}^* \mapsto f : \{0, 1\}^* \) is \( \alpha \)-one-way, if

\[
\Pr_{x \leftarrow \{0, 1\}^n} \left[ A(1^n, f(x)) \in f^{-1}(f(x)) \right] \leq \alpha(n)
\]

for any PPT \( A \) and large enough \( n \in \mathbb{N} \).

1. (strong) OWF according to **Definition 1**, are neg-one-way according to the above definition

2. Can we “amplify" weak OWF to strong ones?
Strong to weak OWFs

Claim 14

Assume there exists OWFs, then there exist functions that are $\frac{2}{3}$-one-way, but not (strong) one-way

Proof: For a OWF $f$, let

$$g(x) = \begin{cases} (1, f(x)), & x_1 = 1; \\ 0, & \text{otherwise } (x_1 = 0). \end{cases}$$
Weak to strong OWFs

**Theorem 15 (weak to strong OWFs (Yao))**

Assume there exist \((1 - \delta)\)-weak OWFs with \(\delta(n) \geq 1/q(n)\) for some \(q \in \text{poly}\), then there exist (strong) one-way functions.

- Idea: parallel repetition (i.e., direct product): Consider 
  \[ g(x_1, \ldots, x_t) = f(x_1), \ldots, f(x_t) \]
  for large enough \(t\)

- Motivation: if something is somewhat hard, than doing it many times is (very) hard

- But, is it really so?
  Consider matrix multiplication: Let \(A \in \mathbb{R}^{n \times n}\) and \(x \in \mathbb{R}^n\)
  Computing \(Ax\) takes \(\Theta(n^2)\) times, but computing \(A(x_1, x_2, \ldots, x_n)\) takes . . . only \(O(n^{2.3\ldots}) < \Theta(n^3)\)

- Fortunately, parallel repetition does amplify weak OWFs :-)}
Amplification via parallel repetition

Theorem 16

Let $f : \{0, 1\}^n \mapsto \{0, 1\}^n$ be a $(1 - \delta)$-weak OWF for $\delta(n) = 1/q(n)$ for some (positive) $q \in \text{poly}$, and let $t(n) = \lceil \log_2 n/\delta(n) \rceil$. Then $g : (\{0, 1\}^n)^{t(n)} \mapsto (\{0, 1\}^n)^{t(n)}$ defined by $g(x_1, \ldots, x_{t(n)}) = f(x_1), \ldots, f(x_{t(n)})$, is a one-way function.

Clearly $g$ is efficient. Is it one-way? Proof via reduction: Assume $\exists \text{ PPT } A$ violating the one-wayness of $g$, we show there exists a PPT $B$ violating the weak hardness of $f$.

**Difficultly**: We need to use an inverter for $g$ with low success probability, e.g., $\frac{1}{n}$, to get an inverter for $f$ with high success probability, e.g., $\frac{1}{2}$ or even $1 - \frac{1}{n}$.

In the following we fix (an assumed) PPT $A$, $p \in \text{poly}$ and infinite set $\mathcal{I} \subseteq \mathbb{N}$ s.t.

$$\Pr_{w \leftarrow \{0,1\}^{t(n) \cdot n}} [A(g(w)) \in g^{-1}(g(w))] \geq 1/p(n)$$

for every $n \in \mathcal{I}$. We also “fix" $n \in \mathcal{I}$ and omit it from the notation.
Proving that $g$ is One-Way – the Naive approach

Assume $A$ attacks each of the $t$ outputs of $g$ independently: $\exists$ PPT $A'$ such that $A(z_1, \ldots, z_t) = A'(z_1) \ldots, A'(z_t)$

It follows that $A'$ inverts $f$ with probability greater than $(1 - \delta)$. Otherwise

$$\Pr\left[ w \leftarrow \{0,1\}^{n \cdot t} \mid A(g(w)) \in g^{-1}(g(w)) \right] = \prod_{i=1}^{t} \Pr\left[ x \leftarrow \{0,1\}^{n} \mid A'(f(x)) \in f^{-1}(f(x)) \right]$$

$$\leq (1 - \delta)^t \leq e^{-\log^2 n} \leq n^{-\log n}$$

Hence $A'$ violates the weak hardness of $f$

A less naive approach would be to assume that $A$ goes over the inputs sequentially.

Unfortunately, we can assume none of the above.

Any idea?
Hardcore sets

Assume \( f \) is of the form

\[
S = \{ S_n \subseteq \{0, 1\}^n \} \text{ is a } \delta\text{-hardcore set for } f: \{0, 1\}^n \mapsto \{0, 1\}^n, \text{ if:}
\]

1. \( \Pr_{x \leftarrow \{0,1\}^n}[f(x) \in S] \geq \delta(n) \) for large enough \( n \), and

2. For any PPT \( A \) and \( q \in \text{poly} \): for large enough \( n \), it holds that
\[
\Pr [A(y) \in f^{-1}(y)] \leq \frac{1}{q(n)} \text{ for every } y \in S_n.
\]

Assuming \( f \) has such a \( \delta \)-HC set seems like a good starting point :-)

Unfortunately, we do not know how to prove that \( f \) has hardcore set :-(
Failing sets

**Definition 18 (failing sets)**

$f : \{0, 1\}^n \mapsto \{0, 1\}^n$ has a $\delta$-failing set for a pair $(A, q)$ of algorithm and polynomial, if exists $S = \{S_n \subseteq \{0, 1\}^n\}$, such that the following holds for large enough $n$:

1. $\Pr_{x \leftarrow \{0,1\}^n} [f(x) \in S_n] \geq \delta(n)$, and
2. $\Pr [A(y) \in f^{-1}(y)] \leq 1/q(n)$, for every $y \in S_n$

**Claim 19**

Let $f$ be a $(1 - \delta)$-OWF, then $f$ has a $\delta/2$-failing set, for any pair of PPT $A$ and $q \in \text{poly}$.

Proof: Assume $\exists$ PPT $A$ and $q \in \text{poly}$, such that for any $S = \{S_n \subseteq \{0, 1\}^n\}$ at least one of the following holds:

1. $\Pr_{x \leftarrow \{0,1\}^n} [f(x) \in S_n] < \delta(n)/2$ for infinitely many $n$’s, or
2. For infinitely many $n$’s: $\exists y \in S_n$ with $\Pr [A(y) \in f^{-1}(y)] \geq 1/q(n)$.

We’ll use $A$ to contradict the hardness of $f$. 

Iftach Haitner (TAU) Foundation of Cryptography February 28, 2019 19 / 26
Using A to invert f

For $n \in \mathbb{N}$, let $S_n := \{y \in \{0, 1\}^n: \Pr[A(y) \in f^{-1}(y)] < 1/q(n)\}$.

**Claim 20**

$\exists$ infinite $\mathcal{I} \subseteq \mathbb{N}$ with $\Pr_{x \leftarrow \{0,1\}^n}[f(x) \in S_n] < \delta(n)/2$ for every $n \in \mathcal{I}$.

**Algorithm 21 (The inverter B on input $y \in \{0,1\}^n$)**

Do (with fresh randomness) for $n \cdot q(n)$ times:
If $x = A(y) \in f^{-1}(y)$, return $x$

Clearly, B is a PPT

**Claim 22**

For $n \in \mathcal{I}$, it holds that $\Pr_{x \leftarrow \{0,1\}^n}[B(f(x)) \in f^{-1}(f(x))] > 1 - \frac{\delta(n)}{2} - 2^{-n}$

Proof: ?

Hence, for large enough $n \in \mathcal{I}$: $\Pr_{x \leftarrow \{0,1\}^n}[B(f(x)) \in f^{-1}(f(x))] > 1 - \delta(n)$. Namely, $f$ is not $(1 - \delta)$-one-way \(\blacksquare\)
**Claim 23**

Assume \( \exists \) PPT \( A, p \in \text{poly} \) and an infinite set \( \mathcal{I} \subseteq \mathbb{N} \) such that

\[
\Pr_{w \leftarrow \{0,1\}^{t(n)\cdot n}} [A(g(x)) \in g^{-1}(g(w))] \geq \frac{1}{p(n)}
\]

for every \( n \in \mathcal{I} \). Then \( \exists \) PPT \( B \) such that

\[
\Pr_{x \leftarrow \{0,1\}^n \mid y = f(x) \in S_n} [B(y) \in f^{-1}(y)] \geq \frac{1}{t(n)p(n)} - n^{-\log n}
\]

for every \( n \in \mathcal{I} \) and every \( S_n \subseteq \{0,1\}^n \) with \( \Pr_{x \leftarrow \{0,1\}^n} [f(x) \in S_n] \geq \delta(n)/2 \).

Fix \( S = \{S_n \subseteq \{0,1\}^n\} \). By Claim 23, for every \( n \in \mathcal{I} \), either

- \( \Pr_{x \leftarrow \{0,1\}^n} [f(x) \in S_n] < \delta(n)/2 \), or
- \( \Pr_{x \leftarrow \{0,1\}^n \mid y = f(x) \in S_n} [B(y) \in f^{-1}(y)] \geq \frac{1}{t(n)p(n)} - n^{-\log n} \)

(for large enough \( n \))

\[
\geq \frac{1}{2t(n)p(n)}
\]

(for large enough \( n \))

\( \Rightarrow \) \( \exists y \in S_n: \Pr [B(y) \in f^{-1}(y)] \geq \frac{1}{2t(n)p(n)} \).
The no failing-set algorithm

Algorithm 24 (Inverter B on input $y \in \{0, 1\}^n$)

1. Choose $w \leftarrow (\{0, 1\}^n)^{t=t(n)}$, $z = (z_1, \ldots, z_t) = g(w)$ and $i \leftarrow [t]$
2. Set $z' = (z_1, \ldots, z_{i-1}, y, z_{i+1}, \ldots, z_t)$
3. Return $A(z')_i$

Fix $n \in \mathcal{I}$ and a set $S_n \subseteq \{0, 1\}^n$ with $\Pr_{x \leftarrow \{0, 1\}^n} [f(x) \in S] \geq \delta(n)/2$.

Claim 25

$$\Pr_{x \leftarrow \{0, 1\}^n | y = f(x) \in S_n} [B(y) \in f^{-1}(y)] \geq \frac{1}{t(n)p(n)} - n^{-\log n}$$
Proving Claim 25

Algorithm 26 (Inverter $B$ on input $y \in \{0, 1\}^n$)

1. Choose $w \leftarrow (\{0, 1\}^n)^{t = t(n)}$, $z = (z_1, \ldots, z_t) = g(w)$ and $i \leftarrow [t]$
2. Set $z' = (z_1, \ldots, z_{i-1}, y, z_{i+1}, \ldots, z_t)$
3. Return $A(z')_i$

Let $Z$ and $Z'$ be values of $z$ and $z'$ in random exe. of $B(f(U_n)|f(U_n) \in S_n)$

Let $Typ = \{v \in (\{0, 1\}^n)^t : \exists i \in [t]: v_i \in S_n\}$.

$Pr_Z[Typ] \geq 1 - n^{-\log n}$

For $L \subseteq \{0, 1\}^{t(n) \cdot n}$:
\[
Pr[Z':= L \cap Typ] = \sum_{\ell \in L'} Pr[Z = \ell] \leq \sum_{\ell \in L'} t(n) \cdot Pr[Z' = \ell] = t(n) \cdot Pr[Z'[L']]
\]

$\implies Pr[Z'[L]] \geq \frac{Pr[Z'[L']]}{t(n)} \geq \frac{Pr[Z] - n^{-\log n}}{t(n)}$. 
Proving Claim 25, cont.

Assume $A$ is deterministic and let $\mathcal{L}_A = \{v \in \{0, 1\}^{t \cdot n} : A(v) \in g^{-1}(v)\}$.

By assumption, $\Pr[Z \in \mathcal{L}_A] \geq 1/p(n)$.

Hence,

$$\Pr_{x \leftarrow \{0, 1\}^n | y = f(x) \in S_n} [B(y) \in f^{-1}(y)] \geq \Pr[Z' \in \mathcal{L}_A]$$

$$\geq \frac{\Pr[Z \in \mathcal{L}_A] - n^{-\log n}}{t(n)}$$

$$\geq \frac{1}{t(n) \cdot p(n)} - n^{-\log n} \square$$
Randomized A

In the case that A is randomized, let

- \( v(n) \) — number of coins A uses on input of length \( nt(n) \).
- \( A_r \) — A whose coins fixed to \( r \)
- \( \alpha_r(n) \) — the inversion probability of \( A_r \) on \( g(U_{nt(n)}) \)

By assumption, \( E_{r \leftarrow \{0,1\}^{v(n)}} [\alpha_r(n)] \geq 1/p(n) \).

Hence,

\[
\Pr_{x \leftarrow \{0,1\}^n \mid y = f(x) \in S_n} \left[ B(y) \in f^{-1}(y) \right] \geq \mathbb{E}_{r \leftarrow \{0,1\}^{v(n)}} \left[ \frac{\alpha_r(n)}{t(n)} - n^{-\log n} \right] \\
= \mathbb{E}_r [\alpha_r(n)] / t(n) - n^{-\log n} \\
\geq \frac{1}{t(n) \cdot p(n)} - n^{-\log n}.
\]
Closing remarks

- Weak OWFs can be amplified into strong one
- Can we give a more security preserving amplification?
- Similar hardness amplification theorems for other cryptographic primitives (e.g., Captchas, general protocols)?
- What properties of the weak OWFs have we used in the proof?
